

Detect procurement-related problems, understand their impact, evaluate possible responses, and produce a recommendation. It does not independently execute high-impact procurement actions.

responsibility is to monitor procurement events, detect procurement risks, analyze their impact, generate possible solutions, and recommend the best response. It does not directly execute high-impact actions.

Procurement Agent is therefore a **domain specialist**, not the overall controller.

It knows about things such as:

- Suppliers
- Purchase Orders
- Purchase Order Items
- Supplier delays
- Procurement risks
- Material availability
- Supplier alternatives
- Procurement response options

It does **not** own:

- Overall cross-domain coordination
- Final enterprise-wide optimization
- Production scheduling
- Inventory control
- Logistics execution

Node 1 — Manual Trigger

What it is

The **Manual Trigger** is our development/testing entry point.

It supplies the event to the Procurement Agent.

Node 2 — Event Validation

This is our first **IF Condition**.

Purpose- Before doing database queries or AI processing, we check whether the incoming event contains the minimum required information.

Node 3 — Execute Query

This is our **database retrieval node**.

We used the PostgreSQL **Execute Query** node connected to the Supabase PostgreSQL database.

Node 4 — Merge Data

This is an important node.

We have two different information sources: Event data , Database data

Node 5 — Risk Detection

This is another **IF Condition**.

Its job is to determine:

Is this event actually a procurement risk that requires further analysis?

Node 6 — Procurement Impact Analysis

This is our AI Transform node.

This is where we move from simple deterministic rules toward intelligence.

Input

It receives the merged procurement context.

Node 7 — Procurement Scenario Analysis

This node generates possible responses.

For our supplier-delay event, we created three scenarios:

Node 8 — Recommendation Check

This is our next IF Condition.

Its current purpose is to check whether our preferred scenario is available.

Node 9 — Procurement Recommendation

This is a Set Fields node.

It converts the selected recommendation into a clean structured object.
